April 20, 2022

Recall our Bayesian Mixture Model

1. Sample the proportions from a Dirichlet prior:

$$\underline{\pi} \sim \mathrm{Dir}(\alpha)$$

2. Sample the parameters for each component:

 $\theta_{\iota} \stackrel{\text{iid}}{\sim} p(\theta \mid \phi, v)$ for k = 1, ..., K

$$z_n \stackrel{\mathsf{iid}}{\sim} \pi$$
 for $n = 1, \dots, N$

(3)

(4)

2/25

 $\mathbf{x}_n \sim p(\mathbf{x} \mid \boldsymbol{\theta}_{z_n})$ for $n = 1, \dots, N$

Joint distribution

► This generative model corresponds to the following factorization of the joint distribution,

$$p(\boldsymbol{\pi}, \{\boldsymbol{\theta}_k\}_{k=1}^K, \{(\boldsymbol{z}_n, \boldsymbol{x}_n)\}_{n=1}^N \mid \boldsymbol{\phi}, \boldsymbol{\nu}, \boldsymbol{\alpha}) = p(\boldsymbol{\pi} \mid \boldsymbol{\alpha}) \prod_{k=1}^K p(\boldsymbol{\theta}_k \mid \boldsymbol{\phi}, \boldsymbol{\nu}) \prod_{n=1}^N p(\boldsymbol{z}_n \mid \boldsymbol{\pi}) p(\boldsymbol{x}_n \mid \boldsymbol{z}_n, \{\boldsymbol{\theta}_k\}_{k=1}^K)$$
(5)

Equivalently,

$$\rho(\boldsymbol{\pi}, \{\boldsymbol{\theta}_k\}_{k=1}^K, \{(z_n, \boldsymbol{x}_n)\}_{n=1}^N \mid \boldsymbol{\phi}, \boldsymbol{v}, \boldsymbol{\alpha}) = \\ \rho(\boldsymbol{\pi} \mid \boldsymbol{\alpha}) \prod_{n=1}^K \rho(\boldsymbol{\theta}_k \mid \boldsymbol{\phi}, \boldsymbol{v}) \prod_{n=1}^K \prod_{k=1}^K \left[\Pr(z_n = k \mid \boldsymbol{\pi}) \rho(\boldsymbol{x}_n \mid \boldsymbol{\theta}_k) \right]^{\mathbb{I}[z_n = k]}$$
(6)

► Substituting in the assumed forms

$$p(\boldsymbol{\pi}, \{\boldsymbol{\theta}_k\}_{k=1}^K, \{(\boldsymbol{z}_n, \boldsymbol{x}_n)\}_{n=1}^N \mid \boldsymbol{\phi}, \boldsymbol{v}, \boldsymbol{\alpha}) = \operatorname{Dir}(\boldsymbol{\pi} \mid \boldsymbol{\alpha}) \prod_{k=1}^K p(\boldsymbol{\theta}_k \mid \boldsymbol{\phi}, \boldsymbol{v}) \prod_{n=1}^N \prod_{k=1}^K [\pi_k p(\boldsymbol{x}_n \mid \boldsymbol{\theta}_k)]^{\mathbb{I}[\boldsymbol{z}_n = k]}$$

Exponential family mixture models

What about $p(\mathbf{x} \mid \boldsymbol{\theta}_k)$ and $p(\boldsymbol{\theta}_k \mid \boldsymbol{\phi}, v)$?

Let's assume an **exponential family** likelihood,

$$p(\mathbf{x} \mid \boldsymbol{\theta}_k) = h(\mathbf{x}_n) \exp \left\{ \langle t(\mathbf{x}_n), \boldsymbol{\theta}_k \rangle - A(\boldsymbol{\theta}_k) \right\}. \tag{8}$$

Then assume a conjugate prior,

$$p(\boldsymbol{\theta}_k \mid \boldsymbol{\phi}, \boldsymbol{v}) \propto \exp\left\{\langle \boldsymbol{\phi}, \boldsymbol{\theta}_k \rangle - vA(\boldsymbol{\theta}_k)\right\}.$$
 (9)

The hyperparmeters ϕ are **pseudo-observations** of the sufficient statistics (like statistics from fake data points) and ν is a **pseudo-count** (like the number of fake data points).

Note that the product of prior and likelihood remains in the same family as the prior. That's why we call it conjugate.

Example: Gaussian mixture model

Assume the conditional distribution of \mathbf{x}_n is a Gaussian with mean $\boldsymbol{\theta}_k \in \mathbb{R}^D$ and identity covariance,

$$\rho(\mathbf{x}_{n} \mid \boldsymbol{\theta}_{k}) = \mathcal{N}(\mathbf{x}_{n} \mid \boldsymbol{\theta}_{k}, \boldsymbol{I})$$

$$= (2\pi)^{-D/2} \exp\left\{-\frac{1}{2}(\mathbf{x}_{n} - \boldsymbol{\theta}_{k})^{\top}(\mathbf{x}_{n} - \boldsymbol{\theta}_{k})\right\}$$

$$= (2\pi)^{-D/2} \exp\left\{-\frac{1}{2}\mathbf{x}_{n}^{\top}\mathbf{x}_{n} + \mathbf{x}_{n}^{\top}\boldsymbol{\theta}_{k} - \frac{1}{2}\boldsymbol{\theta}_{k}^{\top}\boldsymbol{\theta}_{k}\right\},$$

$$(10)$$

$$= (2\pi)^{-D/2} \exp\left\{-\frac{1}{2}\mathbf{x}_{n}^{\top}\mathbf{x}_{n} + \mathbf{x}_{n}^{\top}\boldsymbol{\theta}_{k} - \frac{1}{2}\boldsymbol{\theta}_{k}^{\top}\boldsymbol{\theta}_{k}\right\},$$

which is an exponential family distribution with base measure $h(\mathbf{x}_n) = (2\pi)^{-D/2} e^{-\frac{1}{2}\mathbf{x}_n^{\top}\mathbf{x}_n}$, sufficient statistics $t(\mathbf{x}_n) = \mathbf{x}_n$, and log normalizer $A(\boldsymbol{\theta}_k) = \frac{1}{2}\boldsymbol{\theta}_k^{\top}\boldsymbol{\theta}_k$.

The conjugate prior is a Gaussian prior on the mean,

$$p(\boldsymbol{\theta}_{k} \mid \boldsymbol{\phi}, \boldsymbol{v}) = \mathcal{N}(\boldsymbol{v}^{-1}\boldsymbol{\phi}, \boldsymbol{v}^{-1}\boldsymbol{I}) \propto \exp\left\{\boldsymbol{\phi}^{\top}\boldsymbol{\theta}_{k} - \frac{\boldsymbol{v}}{2}\boldsymbol{\theta}_{k}^{\top}\boldsymbol{\theta}_{k}\right\} = \exp\left\{\boldsymbol{\phi}^{\top}\boldsymbol{\theta}_{k} - \boldsymbol{v}\boldsymbol{A}(\boldsymbol{\theta}_{k})\right\}. \tag{13}$$

Note that ϕ sets the location and ν sets the precision (i.e. inverse variance).

EM in the Gaussian mixture model

K-Means made **hard assignments** of data points to clusters in each iteration. What if we used **soft assignments** instead?

Instead of assigning z_n^* to the closest cluster, we compute *responsibilities* for each cluster:

1. For each data point n and component k, set the *responsibility* to,

conent
$$k$$
, set the *responsibility* to,
$$\omega_{nk} = \frac{\pi_k \mathcal{N}(\mathbf{x}_n \mid \boldsymbol{\theta}_k, \mathbf{I})}{\sum_{j=1}^K \pi_j \mathcal{N}(\mathbf{x}_n \mid \boldsymbol{\theta}_j, \mathbf{I})}. \tag{14}$$

2. For each component *k*, set the new mean to

$$\boldsymbol{\theta}_{k}^{\star} = \frac{1}{N_{k}} \sum_{n=1}^{K} \omega_{nk} \mathbf{x}_{n}, \tag{15}$$

where
$$N_k = \sum_{n=1}^N \omega_{nk}$$
.

This is called the **expectation maximization (EM)** algorithm.

What is EM doing?

Rather than maximizing the joint probability, EM is maximizing the marginal probability,

$$\log p(X, \theta) = \log p(\theta) + \log \sum_{Z \leftarrow \text{ assignment of data points}} p(X, Z \mid \theta)$$
(16)

$$= \log p(\boldsymbol{\theta}) + \log \prod_{n=1}^{N} \sum_{z_{n}} p(\boldsymbol{x}_{n}, z_{n} \mid \boldsymbol{\theta})$$

$$= \log p(\boldsymbol{\theta}) + \log \prod_{n=1}^{N} \sum_{z_{n}} p(\boldsymbol{x}_{n}, z_{n} \mid \boldsymbol{\theta})$$

$$= \log p(\boldsymbol{\theta}) + \log \prod_{n=1}^{N} \sum_{z_{n}} p(\boldsymbol{x}_{n}, z_{n} \mid \boldsymbol{\theta})$$

$$= \log p(\boldsymbol{\theta}) + \log \prod_{n=1}^{N} \sum_{z_{n}} p(\boldsymbol{x}_{n}, z_{n} \mid \boldsymbol{\theta})$$

$$= \log p(\boldsymbol{\theta}) + \log \prod_{n=1}^{N} \sum_{z_{n}} p(\boldsymbol{x}_{n}, z_{n} \mid \boldsymbol{\theta})$$

$$= \log p(\boldsymbol{\theta}) + \log \prod_{n=1}^{N} \sum_{z_{n}} p(\boldsymbol{x}_{n}, z_{n} \mid \boldsymbol{\theta})$$

$$= \log p(\boldsymbol{\theta}) + \log \prod_{n=1}^{N} \sum_{z_{n}} p(\boldsymbol{x}_{n}, z_{n} \mid \boldsymbol{\theta})$$

$$= \log p(\boldsymbol{\theta}) + \log \prod_{n=1}^{N} \sum_{z_{n}} p(\boldsymbol{x}_{n}, z_{n} \mid \boldsymbol{\theta})$$

$$= \log p(\boldsymbol{\theta}) + \log \prod_{n=1}^{N} \sum_{z_{n}} p(\boldsymbol{x}_{n}, z_{n} \mid \boldsymbol{\theta})$$

$$= \log p(\boldsymbol{\theta}) + \log \prod_{n=1}^{N} \sum_{z_{n}} p(\boldsymbol{x}_{n}, z_{n} \mid \boldsymbol{\theta})$$

$$= \log p(\boldsymbol{\theta}) + \log \prod_{n=1}^{N} \sum_{z_{n}} p(\boldsymbol{x}_{n}, z_{n} \mid \boldsymbol{\theta})$$

$$= \log p(\boldsymbol{\theta}) + \log \prod_{n=1}^{N} \sum_{z_{n}} p(\boldsymbol{x}_{n}, z_{n} \mid \boldsymbol{\theta})$$

$$= \log p(\boldsymbol{\theta}) + \log \prod_{n=1}^{N} \sum_{z_{n}} p(\boldsymbol{x}_{n}, z_{n} \mid \boldsymbol{\theta})$$

$$= \log p(\boldsymbol{\theta}) + \log \prod_{n=1}^{N} \sum_{z_{n}} p(\boldsymbol{x}_{n}, z_{n} \mid \boldsymbol{\theta})$$

$$= \log p(\boldsymbol{\theta}) + \sum_{n=1}^{N} \log \sum_{z_n} p(\boldsymbol{x}_n, z_n \mid \boldsymbol{\theta})$$
 (18)

For discrete mixtures (with small enough *K*) we can evaluate the log marginal probability (with what complexity?).

We can usually evaluate its gradient too, so we could just do gradient ascent to find θ^* .

However, EM typically obtains faster convergence rates.

What is EM doing? II

Idea: Obtain a lower bound on the marginal probability,

$$\log p(\mathbf{X}, \boldsymbol{\theta}) = \log p(\boldsymbol{\theta}) + \sum_{n=1}^{N} \log \sum_{z_n} p(\mathbf{x}_n, z_n \mid \boldsymbol{\theta})$$
(19)

$$= \log p(\boldsymbol{\theta}) + \sum_{n=1}^{N} \log \sum_{z_n} q(z_n) \frac{p(\boldsymbol{x}_n, z_n \mid \boldsymbol{\theta})}{q(z_n)}$$
(20)

$$= \log p(\boldsymbol{\theta}) + \sum_{n=1}^{N} \log \mathbb{E}_{q(z_n)} \left[\frac{p(\boldsymbol{x}_n, z_n \mid \boldsymbol{\theta})}{q(z_n)} \right]$$
(21)

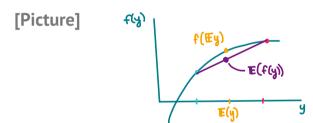

where $q(z_n)$ is any distribution on $z_n \in \{1, ..., K\}$ such that $p(\mathbf{x}_n, z_n \mid \boldsymbol{\theta})$ is **absolutely continuous** w.r.t. $q(z_n)$.

Jensen's Inequality

Jensen's inequality states that,

$$f(\mathbb{E}_{p(y)}[y]) \ge \mathbb{E}_{p(y)}[f(y)] \tag{22}$$

if f is a **concave function**, with equality iff f is linear.

What is EM doing? III

Applied to the log marginal probability, Jensen's inequality yields,

$$\log p(\mathbf{X}, \boldsymbol{\theta}) = \log p(\boldsymbol{\theta}) + \sum_{n=1}^{N} \log \mathbb{E}_{q_n(z_n)} \left[\frac{p(\mathbf{x}_n, z_n \mid \boldsymbol{\theta})}{q_n(z_n)} \right]$$

$$\geq \log p(\boldsymbol{\theta}) + \sum_{n=1}^{N} \mathbb{E}_{q_n(z_n)} \left[\log p(\mathbf{x}_n, z_n \mid \boldsymbol{\theta}) - \log q_n(z_n) \right]$$
(23)

$$\triangleq \mathcal{L}[\boldsymbol{\theta}, \boldsymbol{q}] \tag{25}$$

where $\mathbf{q} = (q_1, \dots, q_N)$ is a tuple of densities.

This is called the **evidence lower bound**, or **ELBO** for short.

It is a function of θ and a functional of q, since each q_n is a probability density function.

We can think of **EM as coordinate ascent on the ELBO**.

M-step: Maximizing the ELBO wrt θ (Gaussian case)

Suppose we fix q. Since each z_n is a discrete latent variable, q_n must be a probability mass function. Let it be denoted by.

$$q_n(z_n) = [q_n(z_n = 1), \dots, q_n(z_n = K)]^{\top} = [\omega_{n1}, \dots, \omega_{nK}]^{\top}.$$

(These will be the **responsibilities** from before.)

Now, recall our basic model, $\mathbf{x}_n \sim \mathcal{N}(\boldsymbol{\theta}_{z_n}, \mathbf{I})$, and assume a prior $\boldsymbol{\theta}_k \sim \mathcal{N}(\boldsymbol{\phi}, v^{-1}\mathbf{I})$, Then,

Then, recall our basic model,
$$\mathbf{x}_n = \mathcal{F}(\mathbf{v}_{\mathbf{z}_n}, \mathbf{r})$$
, and assume a prior $\mathbf{v}_k = \mathcal{F}(\mathbf{\varphi}, \mathbf{v} - \mathbf{r})$, then,

$$\mathscr{L}[\boldsymbol{\theta}, \boldsymbol{q}] = \log p(\boldsymbol{\theta}) + \sum_{n=1}^{N} \mathbb{E}_{q_n(z_n)}[\log p(\boldsymbol{x}_n, z_n \mid \boldsymbol{\theta})] + c$$

$$= \log p(\boldsymbol{\theta}) + \sum_{n=1}^{N} \sum_{k=1}^{K} \omega_{nk} \log p(\boldsymbol{x}_{n}, z_{n} = k \mid \boldsymbol{\theta}) + c$$

$$= \sum_{k=1}^{K} \left[\boldsymbol{\phi}^{\top} \boldsymbol{\theta}_{k} - \frac{v}{2} \boldsymbol{\theta}_{k}^{\top} \boldsymbol{\theta}_{k} \right] + \sum_{n=1}^{N} \sum_{k=1}^{K} \omega_{nk} \left[\boldsymbol{x}_{n}^{\top} \boldsymbol{\theta}_{k} - \frac{1}{2} \boldsymbol{\theta}_{k}^{\top} \boldsymbol{\theta}_{k} \right] + c$$

$$\overline{k=1}$$
 $\overline{n=1}$ $\overline{k=1}$

(26)

(27)

(28)

(29)

M-step: Maximizing the ELBO wrt θ (Gaussian case) II

Zooming in on just θ_k ,

$$\mathcal{L}[\boldsymbol{\theta}, \boldsymbol{q}] = \boldsymbol{\phi}_{N,k}^{\top} \boldsymbol{\theta}_{k} - \frac{1}{2} \nu_{N,k} \boldsymbol{\theta}_{k}^{\top} \boldsymbol{\theta}_{k}$$
(30)

where

$$\boldsymbol{\phi}_{N,k} = \boldsymbol{\phi} + \sum_{n=1}^{N} \omega_{nk} \boldsymbol{x}_{n} \qquad v_{N,k} = v + \sum_{n=1}^{N} \omega_{nk}$$
 (31)

Taking derivatives and setting to zero yields,

$$\boldsymbol{\theta}_{k}^{\star} = \frac{\boldsymbol{\phi}_{N,k}}{v_{N,k}} = \frac{\boldsymbol{\phi} + \sum_{n=1}^{N} \omega_{nk} \boldsymbol{x}_{n}}{v + \sum_{n=1}^{N} \omega_{nk}}.$$
 weighted overage of olds points plus a bias term. (32)

In the improper uniform prior limit where $\phi \to 0$ and $v \to 0$, we recover the EM updates shown on slide 6.

E-step: Maximizing the ELBO wrt q (Gaussian case)

As a function of q_n , for discrete Gaussian mixtures with identity covariance,

$$\mathcal{L}[\boldsymbol{\theta}, \boldsymbol{q}] = \mathbb{E}_{q_n(z_n)} [\log p(\boldsymbol{x}_n, z_n \mid \boldsymbol{\theta}) - \log q_n(z_n)] + c$$

$$\underset{\text{terms}}{\text{conserved}} = \sum_{k=1}^K \omega_{nk} [\log \mathcal{N}(\boldsymbol{x}_n \mid \boldsymbol{\theta}_k, \boldsymbol{I}) + \log \pi_k - \log \omega_{nk}] + c$$

$$\underset{\text{terms}}{\text{conserved}} = \sum_{k=1}^K \omega_{nk} [\log \mathcal{N}(\boldsymbol{x}_n \mid \boldsymbol{\theta}_k, \boldsymbol{I}) + \log \pi_k - \log \omega_{nk}] + c$$
(34)

where $\pi = [\pi_1, \dots, \pi_K]^{\top}$ is the vector of cluster probabilities.

We also have two constraints: $\omega_{nk} \ge 0$ and $\sum_k \omega_{nk} = 1$. Let's **ignore** the non-negative constraint for now (it will automatically be satisfied anyway) and write the Lagrangian with the simplex constraint,

$$\mathscr{J}(\boldsymbol{\omega}_{n}, \lambda) = \sum_{k=1}^{K} \omega_{nk} \left[\log \mathscr{N}(\boldsymbol{x}_{n} \mid \boldsymbol{\theta}_{k}, \boldsymbol{I}) + \log \pi_{k} - \log \omega_{nk} \right] - \lambda \left(1 - \sum_{k=1}^{K} \omega_{nk} \right)$$
(35)

E-step: Maximizing the ELBO wrt q (Gaussian case) II

Taking the partial derivative wrt ω_{nk} and setting to zero yields,

$$\frac{\partial}{\partial \omega_{nk}} \mathscr{J}(\boldsymbol{\omega}_n, \lambda) = \log \mathscr{N}(\boldsymbol{x}_n \mid \boldsymbol{\theta}_k, \boldsymbol{I}) + \log \pi_k - \log \omega_{nk} - 1 + \lambda = 0$$

$$\Rightarrow \log \omega_{nk}^* = \log \mathcal{N}(\mathbf{x}_n \mid \boldsymbol{\theta}_k, \mathbf{I}) + \log \pi_k + \lambda - 1$$

$$\Rightarrow \omega_{nk}^{\star} \propto \pi_k \mathcal{N}(\mathbf{x}_n \mid \boldsymbol{\theta}_k, \mathbf{I})$$

Enforcing the simplex constraint yields,

$$\omega_{nk}^{*} = 1$$

$$\omega_{nk}^{*} = \frac{\pi_{k} \mathcal{N}(\mathbf{x}_{n} \mid \boldsymbol{\theta}_{k}, \boldsymbol{I})}{\sum_{i=1}^{K} \pi_{i} \mathcal{N}(\mathbf{x}_{n} \mid \boldsymbol{\theta}_{i}, \boldsymbol{I})},$$

just like on slide 6.

Note that

$$\omega_{nk}^{\star} \propto p(z_n = k) p(\mathbf{x}_n \mid z_n = k, \boldsymbol{\theta}) = p(z_n = k \mid \mathbf{x}_n, \boldsymbol{\theta})$$

(39)

(36)

(37)

(38)

(40)

14/25

The ELBO is tight after the E-step

Equivalently, q_n equals the posterior, $p(z_n \mid x_n, \theta)$. At that point, the ELBO simplifies to,

$$\mathcal{L}[\boldsymbol{\theta}, \boldsymbol{q}] = \log p(\boldsymbol{\theta}) + \sum_{n=1}^{N} \mathbb{E}_{q_{n}(z_{n})} \left[\log p(\boldsymbol{x}_{n}, z_{n} \mid \boldsymbol{\theta}) - \log q_{n}(z_{n}) \right]$$

$$= \log p(\boldsymbol{\theta}) + \sum_{n=1}^{N} \mathbb{E}_{p(z_{n} \mid \boldsymbol{x}_{n}, \boldsymbol{\theta})} \left[\log p(\boldsymbol{x}_{n}, z_{n} \mid \boldsymbol{\theta}) - \log p(z_{n} \mid \boldsymbol{x}_{n}, \boldsymbol{\theta}) \right]$$

$$= \log p(\boldsymbol{\theta}) + \sum_{n=1}^{N} \mathbb{E}_{p(z_{n} \mid \boldsymbol{x}_{n}, \boldsymbol{\theta})} \left[\log p(\boldsymbol{x}_{n} \mid \boldsymbol{\theta}) \right]$$

$$= \log p(\boldsymbol{\theta}) + \sum_{n=1}^{N} \mathbb{E}_{p(z_{n} \mid \boldsymbol{x}_{n}, \boldsymbol{\theta})} \left[\log p(\boldsymbol{x}_{n} \mid \boldsymbol{\theta}) \right]$$

$$= \log p(\boldsymbol{\theta}) + \sum_{n=1}^{N} \log p(\boldsymbol{x}_{n} \mid \boldsymbol{\theta})$$

$$= \log p(\boldsymbol{X}, \boldsymbol{\theta}) \leftarrow \text{marginal pub!}$$

$$(41)$$

In other words, after the E step, the bound is tight!

EM as a minorize-maximize (MM) algorithm

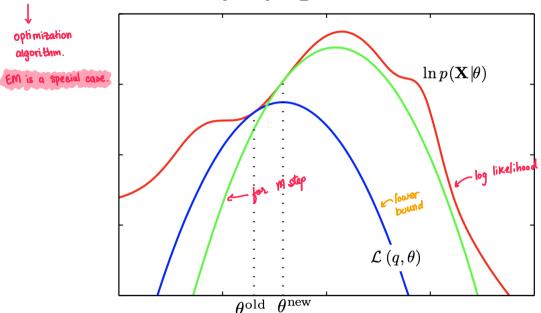

Figure: Bishop, Figure 9.14: EM alternates between constructing a lower bound (minorizing) and finding new parameters that maximize it.

M-step: Maximizing the ELBO wrt θ (generic exp. fam.)

Now let's consider the general Bayesian mixture with exponential family likelihoods and conjugate priors. As a function of θ ,

$$\mathcal{L}[\boldsymbol{\theta}, \boldsymbol{q}] = \log p(\boldsymbol{\theta}) + \sum_{n=1}^{N} \mathbb{E}_{q_n(z_n)}[\log p(\boldsymbol{x}_n, z_n \mid \boldsymbol{\theta})] + c$$
(46)

$$= \log p(\boldsymbol{\theta}) + \sum_{n=1}^{N} \sum_{k=1}^{K} \omega_{nk} \log p(\boldsymbol{x}_{n}, z_{n} = k \mid \boldsymbol{\theta}) + c$$
 (47)

$$= \sum_{k=1}^{K} \left[\boldsymbol{\phi}^{\top} \boldsymbol{\theta}_{k} - \nu A(\boldsymbol{\theta}_{k}) \right] + \sum_{n=1}^{N} \sum_{k=1}^{K} \omega_{nk} \left[t(\boldsymbol{x}_{n})^{\top} \boldsymbol{\theta}_{k} - A(\boldsymbol{\theta}_{k}) \right] + c$$
 (48)

M-step: Maximizing the ELBO wrt heta (generic exp. fam.) II

Zooming in on just θ_k ,

$$\nabla_{\theta_{\mathbf{k}}} \mathcal{A}(\theta, q) = \Phi_{\mathbf{N}\mathbf{k}} - \nabla_{\mathbf{N}\mathbf{k}} \cdot \nabla_{\theta} A(\theta) = 0 \Longrightarrow 0$$

$$\mathcal{L}[\boldsymbol{\theta}, \boldsymbol{q}] = \boldsymbol{\phi}_{N,k}^{\top} \boldsymbol{\theta}_k - \nu_{N,k} A(\boldsymbol{\theta}_k)$$
(49)

where

$$\boldsymbol{\phi}_{N,k} = \boldsymbol{\phi} + \sum_{n=1}^{N} \omega_{nk} t(\boldsymbol{x}_n) \qquad v_{N,k} = v + \sum_{n=1}^{N} \omega_{nk}$$
 (50)

Taking derivatives and setting to zero yields,

$$oldsymbol{ heta}_k^* = \left[
abla A
ight]^{-1} \left(rac{oldsymbol{\phi}_{N,k}}{
u_{N,k}}
ight)$$

(51)

M-step: Maximizing the ELBO wrt θ (generic exp. fam.) III

What is the gradient of the log normalizer? We have,

$$\nabla A(\theta_{k}) = \nabla_{\theta_{k}} \log \int h(\mathbf{x}) \exp \left\{ \langle t(\mathbf{x}), \theta_{k} \rangle \right\} d\mathbf{x}$$

$$= \frac{\int h(\mathbf{x}) \exp \left\{ \langle t(\mathbf{x}), \theta_{k} \rangle \right\} t(\mathbf{x}) d\mathbf{x}}{\int h(\mathbf{x}) \exp \left\{ \langle t(\mathbf{x}), \theta_{k} \rangle \right\} d\mathbf{x} \leftarrow \exp \left\{ A(\theta_{k}) \right\}}$$

$$= \int h(\mathbf{x}) \exp \left\{ \langle t(\mathbf{x}), \theta_{k} \rangle - A(\theta_{k}) \right\} t(\mathbf{x}) d\mathbf{x}$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})} [t(\mathbf{x})] \qquad p(\mathbf{x} \mid \theta_{k})$$

$$= \mathbb{E}_{p(\mathbf{x} \mid \theta_{k})}$$

19/25

M-step: Maximizing the ELBO wrt θ (generic exp. fam.) IV

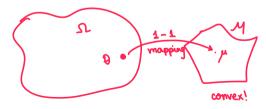

The gradient ∇A is a map from the set of valid natural parameters Ω (those for which the log normalizer is finite) to the set of realizable mean parameters \mathcal{M} , marginal polytope

$$\mathcal{M} = \left\{ \mu \in \mathbb{R}^D : \exists \rho \text{ s.t. } \mathbb{E}_p[t(\mathbf{x})] = \mu \right\}$$
 (56)

An exponential family is minimal if its sufficient statistics are linearly independent.

Fact: The gradient mapping $\nabla A:\Omega\to\mathcal{M}$ is one-to-one (and hence invertible) if and only if the exponential family is minimal.

M-step: Maximizing the ELBO wrt heta (generic exp. fam.) V

Thus, the generic M-step in eq. 51 amounts to finding the natural parameters θ_k^* that yield the expected sufficient statistics $\phi_{N,k}/v_{N,k}$ by inverting the gradient mapping.

Note: There is a longer and much more technical story about exponential families, maximum likelihood, convex analysis, and conjugate duals that you can read about in [Wainwright et al., 2008, Ch. 3] if you are interested.

E-step: Maximizing the ELBO wrt q (generic exp. fam.)

In our first pass, we assumed q_n was a finite pmf. More generally, q_n will be a probability density function, and optimizing over functions usually requires the **calculus of variations**. (Ugh!)

However, note that we can write the ELBO in a slightly different form,

$$\mathcal{L}[\boldsymbol{\theta}, \boldsymbol{q}] = \log p(\boldsymbol{\theta}) + \sum_{n=1}^{N} \mathbb{E}_{q_{n}(z_{n})} \left[\log p(\boldsymbol{x}_{n}, z_{n} \mid \boldsymbol{\theta}) - \log q_{n}(z_{n}) \right]$$

$$= \log p(\boldsymbol{\theta}) + \sum_{n=1}^{N} \mathbb{E}_{q_{n}(z_{n})} \left[\log p(z_{n} \mid \boldsymbol{x}_{n}, \boldsymbol{\theta}) + \log p(\boldsymbol{x}_{n} \mid \boldsymbol{\theta}) - \log q_{n}(z_{n}) \right]$$

$$= \log p(\boldsymbol{\theta}) + \sum_{n=1}^{N} \left[\log p(\boldsymbol{x}_{n} \mid \boldsymbol{\theta}) - D_{KL} \left(q_{n}(z_{n}) \parallel p(z_{n} \mid \boldsymbol{x}_{n}, \boldsymbol{\theta}) \right) \right]$$

$$= \log p(\boldsymbol{X}, \boldsymbol{\theta}) - \sum_{n=1}^{N} D_{KL} \left(q_{n}(z_{n}) \parallel p(z_{n} \mid \boldsymbol{x}_{n}, \boldsymbol{\theta}) \right)$$

$$= \log p(\boldsymbol{X}, \boldsymbol{\theta}) - \sum_{n=1}^{N} D_{KL} \left(q_{n}(z_{n}) \parallel p(z_{n} \mid \boldsymbol{x}_{n}, \boldsymbol{\theta}) \right)$$

$$= \log p(\boldsymbol{X}, \boldsymbol{\theta}) - \sum_{n=1}^{N} D_{KL} \left(q_{n}(z_{n}) \parallel p(z_{n} \mid \boldsymbol{x}_{n}, \boldsymbol{\theta}) \right)$$

$$= \log p(\boldsymbol{X}, \boldsymbol{\theta}) - \sum_{n=1}^{N} D_{KL} \left(q_{n}(z_{n}) \parallel p(z_{n} \mid \boldsymbol{x}_{n}, \boldsymbol{\theta}) \right)$$

$$= \log p(\boldsymbol{X}, \boldsymbol{\theta}) - \sum_{n=1}^{N} D_{KL} \left(q_{n}(z_{n}) \parallel p(z_{n} \mid \boldsymbol{x}_{n}, \boldsymbol{\theta}) \right)$$

$$= \log p(\boldsymbol{X}, \boldsymbol{\theta}) - \sum_{n=1}^{N} D_{KL} \left(q_{n}(z_{n}) \parallel p(z_{n} \mid \boldsymbol{x}_{n}, \boldsymbol{\theta}) \right)$$

$$= \log p(\boldsymbol{X}, \boldsymbol{\theta}) - \sum_{n=1}^{N} D_{KL} \left(q_{n}(z_{n}) \parallel p(z_{n} \mid \boldsymbol{x}_{n}, \boldsymbol{\theta}) \right)$$

$$= \log p(\boldsymbol{X}, \boldsymbol{\theta}) - \sum_{n=1}^{N} D_{KL} \left(q_{n}(z_{n}) \parallel p(z_{n} \mid \boldsymbol{x}_{n}, \boldsymbol{\theta}) \right)$$

$$= \log p(\boldsymbol{X}, \boldsymbol{\theta}) - \sum_{n=1}^{N} D_{KL} \left(q_{n}(z_{n}) \parallel p(z_{n} \mid \boldsymbol{x}_{n}, \boldsymbol{\theta}) \right)$$

$$= \log p(\boldsymbol{X}, \boldsymbol{\theta}) - \sum_{n=1}^{N} D_{KL} \left(q_{n}(z_{n}) \parallel p(z_{n} \mid \boldsymbol{x}_{n}, \boldsymbol{\theta}) \right)$$

$$= \log p(\boldsymbol{X}, \boldsymbol{\theta}) - \sum_{n=1}^{N} D_{KL} \left(q_{n}(z_{n}) \parallel p(z_{n} \mid \boldsymbol{x}_{n}, \boldsymbol{\theta}) \right)$$

where $D_{\mathrm{KL}}\left(\cdot \parallel \cdot \right)$ denote the **Kullback-Leibler divergence**.

Kullback-Leibler (KL) divergence

The KL divergence is defined as,

$$D_{\mathrm{KL}}(q(z) \parallel p(z)) = \int q(z) \log \frac{q(z)}{p(z)} \, \mathrm{d}z. \tag{61}$$

It gives a notion of how similar two distributions are, but it is **not a metric!** (It is not symmetric, e.g.) Still, it has some intuitive properties:

- ► It is non-negative, $D_{KL}(q(z) || p(z)) \ge 0$.
- ► It equals zero iff the distributions are the same, $D_{\text{KL}}\left(q(z)\parallel p(z)\right)=0\iff q(z)=p(z)$ almost everywhere.

doesn't satisfy triangle inequality.

E-step: Maximizing the ELBO wrt q (generic exp. fam.) II

Maximizing the ELBO wrt q_n amounts to minimizing the KL divergence to the posterior $p(z_n \mid \mathbf{x}_n, \boldsymbol{\theta})$,

$$\mathscr{L}[\boldsymbol{\theta}, \boldsymbol{q}] = \log p(\boldsymbol{\theta}) + \sum_{n=1}^{N} [\log p(\boldsymbol{x}_n \mid \boldsymbol{\theta}) - D_{\mathrm{KL}}(q_n(z_n) \parallel p(z_n \mid \boldsymbol{x}_n, \boldsymbol{\theta}))]$$

$$= -D_{\mathrm{KL}}(q_n(z_n) \parallel p(z_n \mid \boldsymbol{x}_n, \boldsymbol{\theta})) + c$$

As we said, the KL is minimized when $q_n(z_n) = p(z_n \mid \boldsymbol{x}_n, \boldsymbol{\theta})$, so the optimal update is,

$$q_n^{\star}(z_n) = p(z_n \mid \boldsymbol{x}_n, \boldsymbol{\theta}),$$

just like we found on slide 14.
